

Chandra Science Highlight

A Likely Decade Long Black Hole Tidal Disruption Event

The artist's illustration depicts a "tidal disruption event," in which a star is destroyed by tidal forces from a supermassive black hole. Some stellar debris is flung out at high speeds (blue), while the rest (red) falls toward the black hole, generating an X-ray flare. The insets show the optical and X-ray images of the dwarf galaxy SDSS J150052.07+015453.8

CXC Operated for NASA by the Smithsonian Astrophysical Observatory

- An X-ray source was detected serendipitously in observations by Chandra and XMM-Newton of a foreground galaxy group from 2005 to 2011.
- In 2005, the source flared up by a factor of 100 over a period of a few months and has decayed by only a factor ~2 over the next decade.
- An observation with Chandra in 2015 provided a well constrained X-ray position coincident with the center of a dwarf galaxy.
- The proposed explanation for this event is the tidal disruption of a star by a supermassive black hole in the center of the dwarf galaxy. If so, the decade-long flare has persisted much longer than the typical duration of ~ 1 year tidal disruption events.

Scale: Inset images are 11 arcsec across (about 92,000 light years) Distance: About 1.8 billion light years
